## **Processing Lines**

We mentioned four commands that process lines: cut, tr, uniq and sort.

The **cut** command will split the line by some given parameter. You can define that parameter with the **d** option.

The **f** option will then define which piece of data you want to take, after the line splitting.

**tr** stands for translate. It will literally replace characters. The first argument are the characters you want to replace and the second argument are the ones you want to replace them with.

uniq command will only leave the unique lines.

**sort** will sort the lines by numbers or the alphabet.
